one or two very extreme residuals cause a rejection of the normality assumption. Such observations would appear in the tails of the distribution, and would therefore lead us, which enters into the definition of kurtosis, to be very large. Such observations that do not fit in with the pattern of the remainder of the data are known as outliers. Outliers are not necessarily a problem for the regression model, as long as they do not affect the overall fit of the model. In fact, outliers can be useful in that they can help to identify areas where the model is not working well. For example, if a particular observation has a very high residual, this could indicate that there is a change in the underlying process, or that there is a structural break in the data. In such cases, the outlier can be used to identify the break, and the model can be re-estimated for the period before and after the break. This is a useful technique for identifying and dealing with outliers in regression analysis.

As an example, suppose we have a regression model with two explanatory variables,  $x_1$  and  $x_2$ , and a dependent variable  $y$ . The regression equation is  $y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \epsilon$ , where  $\epsilon$  is the error term. Suppose we have a set of data points, and we find that one observation has a very high residual. This could indicate that there is a change in the underlying process, or that there is a structural break in the data. In such cases, the outlier can be used to identify the break, and the model can be re-estimated for the period before and after the break. This is a useful technique for identifying and dealing with outliers in regression analysis.

Another example is the case of a regression model where the error term is not normally distributed. This could be due to a variety of reasons, such as the presence of outliers, or the presence of a non-linear relationship between the variables. In such cases, the residuals will not be normally distributed, and this will affect the validity of the regression model. To deal with this, we can use a variety of techniques, such as transforming the data, or using a different distribution for the error term.

In conclusion, outliers and non-normality are important issues in regression analysis. They can affect the validity of the model, and can lead to misleading results. However, there are a variety of techniques available to deal with these issues, and it is important to be aware of them when using regression analysis.

5.1.1. Regression residuals from stock return data, showing large outlier for October 1987. A new variable called DR7M100 could be defined as DR7M100 = 1 during October 1987 and zero otherwise. The observations for the dummy variable would appear as in Box 5.6. The dummy variable would then be used just like any other variable in the regression model, e.g., (5.50) This type of dummy variable that takes the value one for only a single observation has an effect exactly equivalent to knocking out that observation from the sample altogether, by forcing the residual for that observation to zero. The estimated coefficient on the dummy variable will be equal to the residual that the dummied observation would have taken if the dummy variable had not been included. BOX 5.6 Observations for the dummy variable 289 Time Value of dummy variable DR7M100 1986M12 0 1987M01 0 : : : 1987M09 1987M10 1 1987M11 0 : : However, many econometricians would argue that dummy variables to remove outlying residuals can be used to artificially improve the characteristics of the model – in essence fudging the results. Removing outlying observations will reduce standard errors, reduce the RSS, and therefore increase R2, thus improving the apparent fit of the model to the data. The removal of observations is also hard to reconcile with the notion in statistics that each data point represents a useful piece of information. The other side of this argument is that observations that are a 'long way away' from the rest, and seem not to fit in with the general pattern of the rest of the data are known as outliers. Outliers can have a serious effect on OLS estimation estimates since, by definition, OLS will receive a big penalty, in the form of an increased RSS for points that are a long way from the fitted line. Consequently, OLS will try extra hard to minimise the distances of points that would have otherwise been a long way from the line. A graphical depiction of the possible effect of an outlier on OLS estimation is shown in Figure 5.10. Figure 5.10 shows a regression line fitted to a set of data points. One point is an outlier, and is far from the rest of the data. The regression line is pulled towards the outlier, and the slope is affected. The outlier is also far from the rest of the data, and the regression line is pulled towards the outlier, and the slope is affected. The outlier is also far from the rest of the data, and the regression line is pulled towards the outlier, and the slope is affected.

5.1.2. Relationship between  $y$  and  $x_2$  in a quadratic regression for different values of  $\beta_2$  and  $\beta_3$  We could add even higher order terms to equation (5.55), such as a cubic or quartic term. It might be that a cubic would be useful to capture something like a point of inflection, where the relationship between  $x$  and  $y$  has a stationary point but it is rare that we would be able to justify any higher order term than a quadratic from the perspective of its relevance. An alternative possibility is that the relationship between  $x$  and  $y$  is non-linear, but the non-linearity is not captured by a quadratic term. In such cases, we can use a higher order polynomial, such as a cubic or quartic term. This is a common technique for dealing with non-linear relationships in regression analysis.

5.1.3. Measurement Errors As stated above, one of the of the assumptions of the classical linear regression model is that the explanatory variables are non-stochastic. One way in which this assumption can be violated is when there is a two-way causal relationship between the explanatory and explained variable, and this situation is known as simultaneous causality. In such cases, the explanatory variables are not exogenous, and this will affect the validity of the regression model. To deal with this, we can use a variety of techniques, such as using instrumental variables, or using a structural equation model.

5.1.4. Measurement Error in the Explanatory Variable(s) For simplicity, suppose that we wish to estimate a model containing just one explanatory variable,  $x$ , and a dependent variable,  $y$ . The regression equation is  $y = \beta_0 + \beta_1 x + \epsilon$ , where  $\epsilon$  is the error term. Suppose that the explanatory variable,  $x$ , is measured with error. This will affect the validity of the regression model, and will lead to biased estimates of the coefficients. To deal with this, we can use a variety of techniques, such as using instrumental variables, or using a structural equation model.

5.1.5. Determinants of Sovereign Credit Ratings 5.1.5.1. Background Sovereign credit ratings are an assessment of the riskiness of debt issued by governments. They embody an estimate of the probability that the borrower will default on her obligation. Two famous US ratings agencies, Moody's and Standard and Poor's (S&P), provide ratings for many governments. Although the two agencies use different symbols to denote the given riskiness of a particular borrower, the ratings of the two agencies are comparable. Gradings are split into two broad categories: investment grade and speculative grade. Investment grade issuers have good or adequate payment capacity, while speculative grade issuers either have a high degree of uncertainty about whether they will make their payments, or are already in default. The highest grade offered by the agencies, for the highest quality of credit, is AAA. The lowest grade is D, which indicates that the issuer is in default. The agencies use a variety of factors to determine the ratings, and these factors are listed in Table 5.2. The agencies use a variety of factors to determine the ratings, and these factors are listed in Table 5.2. The agencies use a variety of factors to determine the ratings, and these factors are listed in Table 5.2.

5.1.5.2. Determinants and Impacts of Sovereign Credit Ratings Dependent Variable: Explanatory Variable (1) Expected sign (2) Average rating (3) Moody's rating (4) S&P rating (5) Difference Moody's/S&P (6) Intercept (7) 1.442 (0.663) 3.408 (1.379) -0.524 (-0.223) 3.932 (2.521) Per capita income + 1.242\*\*\* (5.302) 1.027\*\*\* (4.041) 1.458\*\*\* (6.048) -0.431 (-2.688) GDP growth + 0.151 (1.935) 1.103 (1.545) 0.171\*\* (2.132) -0.040 (0.756) Inflation - 0.611\*\*\* (-2.839) -0.630\*\*\* (-2.701) -0.591\*\*\* (-2.671) -0.039 (-0.265) Fiscal + 0.073 0.049 0.097\* -0.048 319 balance (1.324) (0.818) 1.751 (-1.274) External debt + 0.003 (0.314) 0.006 (0.535) 0.001 (0.046) 0.006 (0.779) External debt - 0.013\*\*\* (-5.088) -0.015\*\*\* (-5.365) -0.011\*\*\* (-4.236) -0.004 (-2.133) Development dummy + 2.776\*\*\* (4.25) 2.957\*\*\* (4.175) 2.595\*\*\* (3.861) 0.362 (0.81) Default dummy - 2.042\*\*\* (-3.175) -1.633\*\*\* (-2.097) -2.622\*\*\* (-3.962) 1.159 (2.632) 0.924 0.905 0.926 0.836 Adjusted R2 Notes: t-ratios in parentheses; \*, \*\*, and \*\*\* indicate significance at the 10%, 5% and 1% levels, respectively. Source: Cantor and Packer (1996). Reprinted with permission from Institutional Investor. 5.15.3. Interpretation of the Models The models are difficult to interpret in terms of their statistical adequacy, since virtually no diagnostic tests have been undertaken. The values of the adjusted R2, at over 90% for each of the three ratings regressions, are high for cross-sectional regressions, indicating that the model seems able to capture almost all of the variability of the ratings. The statistical adequacy of the model is also supported by the fact that the adjusted R2 is high for each of the three ratings regressions. The statistical adequacy of the model is also supported by the fact that the adjusted R2 is high for each of the three ratings regressions.

5.1.5.4. Conclusions To summarise, six factors appear to play a big role in determining sovereign credit ratings – income, GDP growth, inflation, external debt, interest rates and not default history. The ratings provide more information than the average score alone. The dependent variable is now the log of the yield spread, i.e.,  $\ln(\text{yield} - \text{treasury yield})$ . In yield on the sovereign bond. One may argue that such a measure is not a good measure of risk, for the true credit spread should be defined by the difference in credit quality rather than by just two points. It is however, leaving this issue aside, the results are presented in Table 5.3. Table 5.3 Do ratings add to public information? Variable: Expected sign Dependent variable: (1) Spread (2) 1.027\*\*\* (4.041) 1.458\*\*\* (6.048) -0.431 (-2.688) GDP growth + 0.151 (1.935) 1.103 (1.545) 0.171\*\* (2.132) -0.040 (0.756) Inflation - 0.611\*\*\* (-2.839) -0.630\*\*\* (-2.701) -0.591\*\*\* (-2.671) -0.039 (-0.265) Fiscal + 0.073 0.049 0.097\* -0.048 319 balance (1.324) (0.818) 1.751 (-1.274) External debt + 0.003 (0.314) 0.006 (0.535) 0.001 (0.046) 0.006 (0.779) External debt - 0.013\*\*\* (-5.088) -0.015\*\*\* (-5.365) -0.011\*\*\* (-4.236) -0.004 (-2.133) Development dummy + 2.776\*\*\* (4.25) 2.957\*\*\* (4.175) 2.595\*\*\* (3.861) 0.362 (0.81) Default dummy - 2.042\*\*\* (-3.175) -1.633\*\*\* (-2.097) -2.622\*\*\* (-3.962) 1.159 (2.632) 0.924 0.905 0.926 0.836 Adjusted R2 Notes: t-ratios in parentheses; \*, \*\*, and \*\*\* indicate significance at the 10%, 5% and 1% levels, respectively. Source: Cantor and Packer (1996). Reprinted with permission from Institutional Investor. 5.15.4. Interpreting the Models The models are difficult to interpret in terms of their statistical adequacy, since virtually no diagnostic tests have been undertaken. The values of the adjusted R2, at over 90% for each of the three ratings regressions, are high for cross-sectional regressions, indicating that the model seems able to capture almost all of the variability of the ratings. The statistical adequacy of the model is also supported by the fact that the adjusted R2 is high for each of the three ratings regressions. The statistical adequacy of the model is also supported by the fact that the adjusted R2 is high for each of the three ratings regressions.

5.1.5.5. How the Market Reacts to Ratings Announcements? Cantor and Packer also consider whether it is possible to build a model to predict how the market will react to ratings announcements, in terms of the resulting change in the yield spread. The dependent variable for this set of regressions is now the change in the log of the relative spread, i.e.,  $\ln(\text{yield} - \text{treasury yield})$ , over a two-day period at the time of the announcement. The sample employed for estimation comprises every announcement of a ratings change that occurred between 1987 and 1994; seventy-nine such announcements were made, spread over eighteen countries. Of these, thirty-nine were actual ratings changes by one or more of the agencies, and forty were listed as likely in the near future to experience a regrading. Moody's calls this a 'watchlist', while S&P terms their 'outlook' list. The explanatory variables are mainly dummy variables for whether the announcement was positive – i.e., an upgrade rather than a downgrade – or whether there was an actual ratings change or just listing for probable 323 regrading whether the announcement was made by Moody's or S&P; whether the bond was speculative grade or investment grade; whether there had been another ratings change in the two days before the announcement; and whether the announcement was made by Moody's or S&P. The regression results are presented in Table 5.4. What determines reactions to ratings announcements? Dependent variable: Log relative spread (Intercept) -0.02 (-1.4) Positive announcements 0.01 (0.34) Ratings changes -0.01 (-0.37) Moody's announcements 0.02 (1.51) Speculative grade 0.03\*\* (2.33) Change in relative spreads from day -60 to day -1 -0.06 (-1.1) Rating gap 0.03\* (1.7) Other rating announcements from day -60 to day -1 0.05\*\* (2.15) 324 Adjusted R2 0.12 Note: \*, \*\*, and \*\*\* denote significance at the 10% and 5% levels, respectively. Source: Cantor and Packer (1996). Reprinted with permission from Institutional Investor. As can be seen from Table 5.4, the models appear to do a relatively poor job of explaining how the market will react to ratings announcements. The adjusted R2 value is only 12%, and this is the highest of the five specifications tested by the authors. Further, only two variables are significant and one marginally significant of the seven employed in the model. It can therefore be stated that yield changes are significantly higher following a ratings announcement for speculative than investment grade bonds, and that ratings changes have a bigger impact on yield spreads if there is an agreement between the ratings agencies at the time the announcement is made. Further, yields change significantly more if there has been a previous announcement in the past sixty days than if not. On the other hand, neither whether the announcement is an upgrade or a downgrade, nor whether it is an actual ratings change or a name on the watchlist, nor whether the announcement is made by Moody's or S&P, nor the amount by which the relative spread has already changed over the past sixty days, has any significant impact on how the market reacts to ratings announcements. 5.15.6. Conclusions To summarise, six factors appear to play a big role in determining sovereign credit ratings – income, GDP growth, inflation, external debt, interest rates and not default history. The ratings provide more information than the average score alone. The dependent variable is now the log of the yield spread, i.e.,  $\ln(\text{yield} - \text{treasury yield})$ . In yield on the sovereign bond. One may argue that such a measure is not a good measure of risk, for the true credit spread should be defined by the difference in credit quality rather than by just two points. It is however, leaving this issue aside, the results are presented in Table 5.3. Table 5.3 Do ratings add to public information? The statistical adequacy of the model is also supported by the fact that the adjusted R2 is high for each of the three ratings regressions.

5.1.5.7. What pattern(s) would one like to see in a residual plot and why? 3. A researcher estimates the following model for stock market returns, but thinks that there may be a problem with it. By calculating the t-ratios and considering their significance and by examining the value of R2 otherwise, suggest what the problem might be. (5.81) How might you go about solving the perceived problem? (a) State in algebraic notation and explain the assumption about the CLRM's disturbances that is referred to by the term 'homoscedasticity'. (b) What would the consequence be for a regression model if the errors were not homoscedastic? (c) How might you proceed if you found that (b) were actually 326 5. (a) (b) (c) the case? What do you understand by the term 'autocorrelation'? An econometrician suspects that the residuals of her model might be autocorrelated. Explain the steps involved in testing this theory using the Durbin-Watson (DW) test. The econometrician follows your guidance (!!!) in part (b) and calculates a value for the Durbin-Watson statistic of 0.95. The regression has sixty quarterly observations and three explanatory variables (plus a constant term). Perform the test. What is your conclusion? In order to allow for autocorrelation, the econometrician decides to use a model in first differences with a constant (5.82) By attempting to calculate the long-run solution to this model, explain what might be a problem with estimating models entirely in first differences. (e) The econometrician finally settles on a model with both first differences and lagged levels terms of the variables (5.83) Can the Durbin-Watson test still validly be used in this case? (f) Calculate the long-run static equilibrium solution to the following dynamic econometric model (5.84) 7. What might Ramsey's RESET test be used for? What could be done if it were found that the RESET test has been failed? (g) Why is it necessary to assume that the disturbances of a regression model are normally distributed? (h) In a practical econometric

Calculated? 4.4 Testing Multiple Hypotheses: The F-test 4.5 Data Mining and the True Size of the Test 4.6 Qualitative Variables 4.7 Goodness of Fit Statistics 4.8 Hedonic Pricing Models 4.9 Tests of Non-Nested Hypotheses 4.10 Quantile Regression Appendix 4.1 Mathematical Derivations of CLRM Results Appendix 4.2 A Brief Introduction to Factor Models and Principal Components Analysis Chapter 5 Classical Linear Regression Model Assumptions and Diagnostic Tests 5.1 Introduction 209 210 212 214 222 223 225 230 234 236 242 245 254 254 885 5.2 Statistical Distributions for Diagnostic Tests 5.3 Assumption (1):  $E(u_i) = 0$  5.4 Assumption (2):  $\text{var}(u_i) = \sigma^2 < \infty$  5.5 Assumption (3):  $\text{cov}(u_i, u_j) = 0$  for  $i \neq j$  5.6 Assumption (4): The  $x_t$  are Non-Stochastic 5.7 Assumption (5): The Disturbances are Normally Distributed 5.8 Multicollinearity 5.9 Adopting the Wrong Functional Form 5.10 Omission of an Important Variable 5.11 Inclusion of an Irrelevant Variable 5.12 Parameter Stability Tests 5.13 Measurement Errors 5.14 A Strategy for Constructing Econometric Models 5.15 Determinants of Sovereign Credit Ratings Chapter 6 Univariate Time-Series Modelling and Forecasting 6.1 Introduction 6.2 Some Notation and Concepts 6.3 Moving Average Processes 6.4 Autoregressive Processes 6.5 The Partial Autocorrelation Function 6.6 ARMA Processes 6.7 Building ARMA Models: The Box-Jenkins Approach 6.8 Examples of Time-Series Modelling in Finance 6.9 Exponential Smoothing 6.10 Forecasting in Econometrics Chapter 7 Multivariate Models 7.1 Motivations 7.2 Simultaneous Equations Bias 7.3 So how can Simultaneous Equations Models be Validly Estimated? 7.4 Can the Original Coefficients be Retrieved from the  $\pi$  s? 7.5 Simultaneous Equations in Finance 7.6 A Definition of Exogeneity 886 255 256 257 264 286 287 292 296 300 301 302 311 313 317 330 330 331 336 340 349 351 358 361 364 367 387 387 390 391 392 395 396 7.7 Triangular Systems 7.8 Estimation Procedures for Simultaneous Equations Systems 7.9 An Application of a Simultaneous Equations Approach 7.10 Vector Autoregressive Models 7.11 Does the VAR Include Contemporaneous Terms? 7.12 Block Significance and Causality Tests 7.13 VARs with Exogenous Variables 7.14 Impulse Responses and Variance Decompositions 7.15 VAR Model Example: The Interaction Between Property Returns and the Macroeconomy 7.16 A Couple of Final Points on VARs 399 400 404 410 417 420 422 422 426 433 Chapter 8 Modelling Long-Run Relationships in Finance 437 8.1 Stationarity and Unit Root Testing 8.2 Tests for Unit Roots in the Presence of Structural Breaks 8.3 Cointegration 8.4 Equilibrium Correction or Error Correction Models 8.5 Testing for Cointegration in Regression: A Residuals-Based Approach 8.6 Methods of Parameter Estimation in Cointegrated Systems 8.7 Lead-Lag and Long-Term Relationships Between Spot and Futures Markets 8.8 Testing for and Estimating Cointegration in Systems 8.9 Purchasing Power Parity 8.10 Cointegration Between International Bond Markets 8.11 Testing the Expectations Hypothesis of the Term Structure of Interest Rates Chapter 9 Modelling Volatility and Correlation 9.1 Motivations: An Excursion into Non-Linearity Land 9.2 Models for Volatility 9.3 Historical Volatility 9.4 Implied Volatility Models 9.5 Exponentially Weighted Moving Average Models 9.6 Autoregressive Volatility Models 9.7 Autoregressive Conditionally Heteroscedastic (ARCH) Models 887 437 453 457 460 462 463 464 474 480 482 489 497 497 503 504 504 504 506 506 9.8 Generalised ARCH (GARCH) Models 9.9 Estimation of ARCH/GARCH Models 9.10 Extensions to the Basic GARCH Model 9.11 Asymmetric GARCH Models 9.12 The GJR model 9.13 The EGARCH Model 9.14 Tests for Asymmetries in Volatility 9.15 GARCH-in-Mean 9.16 Uses of GARCH-Type Models 9.17 Testing Non-Linear Restrictions 9.18 Volatility Forecasting: Some Examples and Results 9.19 Stochastic Volatility Models Revisited 9.20 Forecasting Covariances and Correlations 9.21 Covariance Modelling and Forecasting in Finance 9.22 Simple Covariance Models 9.23 Multivariate GARCH Models 9.24 Direct Correlation Models 9.25 Extensions to the Basic Multivariate GARCH Model 9.26 A Multivariate GARCH Model for the CAPM 9.27 Estimating a Time-Varying Hedge Ratio 9.28 Multivariate Stochastic Volatility Models Appendix 9.1 Parameter Estimation Using Maximum Likelihood Chapter 10 Switching and State Space Models 10.1 Motivations 10.2 Seasonalities in Financial Markets 10.3 Modelling Seasonality in Financial Data 10.4 Estimating Simple Piecewise Linear Functions 10.5 Markov Switching Models 10.6 A Markov Switching Model for the Real Exchange Rate 10.7 A Markov Switching Model for the Gilt-Equity Yield Ratio 10.8 Threshold Autoregressive Models 10.9 Estimation of Threshold Autoregressive Models 10.10 Specification Tests 10.11 A SETAR Model for the French franc-German mark 888 512 515 520 521 521 522 523 525 526 529 532 541 544 545 547 549 553 556 557 559 563 565 573 573 576 577 586 588 590 592 597 599 601 Exchange Rate 10.12 Threshold Models for FTSE Spot and Futures 10.13 Regime Switching Models and Forecasting 10.14 State Space Models and the Kalman Filter Chapter 11 Panel Data 605 610 610 625 11.1 Introduction: What Are Panel Techniques? 11.2 What Panel Techniques Are Available? 11.3 The Fixed Effects Model 11.4 Time-Fixed Effects Models 11.5 Investigating Banking Competition 11.6 The Random Effects Model 11.7 Panel Data Application to Credit Stability of Banks 11.8 Panel Unit Root and Cointegration Tests 11.9 Further Feading Chapter 12 Limited Dependent Variable Models 12.1 Introduction and Motivation 12.2 The Linear Probability Model 12.3 The Logit Model 12.4 Using a Logit to Test the Pecking Order Hypothesis 12.5 The Probit Model 12.6 Choosing Between the Logit and Probit Models 12.7 Estimation of Limited Dependent Variable Models 12.8 Goodness of Fit Measures for Linear Dependent Variable Models 12.9 Multinomial Linear Dependent Variables 12.10 The Pecking Order Hypothesis Revisited 12.11 Ordered Response Linear Dependent Variables Models 12.12 Are Unsolicited Credit Ratings Biased Downwards? An Ordered Probit Analysis 12.13 Censored and Truncated Dependent Variables Appendix 12.1 The Maximum Likelihood Estimator for Logit and Probit Models Chapter 13 Simulation Methods 13.1 Motivations 625 627 628 630 632 636 639 643 653 657 657 658 660 661 664 664 666 666 672 675 676 681 689 692 692 889 13.1 Motivations 13.2 Monte Carlo Simulations 13.3 Variance Reduction Techniques 13.4 Bootstrapping 13.5 Random Number Generation 13.6 Disadvantages of the Simulation Approach 13.7 An Example of Monte Carlo Simulation 13.8 An Example of how to Simulate the Price of a Financial Option 13.9 An Example of Bootstrapping to Calculate Capital Risk Requirements Chapter 14 Additional Econometric Techniques for Financial Research 692 693 695 699 704 705 706 708 710 723 14.1 Event Studies 14.2 Tests of the CAPM and the Fama-French Methodology 14.3 Extreme Value Theory 14.4 The Generalised Method of Moments 724 740 749 766 Chapter 15 Conducting Empirical Research or Doing a Project or Dissertation in Finance 780 15.1 What is an Empirical Research Project? 15.2 Selecting the Topic 15.3 Sponsored or Independent Research? 15.4 The Research Proposal 15.5 Working Papers and Literature on the Internet 15.6 Getting the Data 15.7 Choice of Computer Software 15.8 Methodology 15.9 How Might the Finished Project Look? 15.10 Presentational Issues Appendix 1 Sources of Data Used in This Book and the Accompanying Software Manuals Appendix 2 Tables of Statistical Distributions Glossary 890 780 781 786 787 788 790 790 791 791 797 798 800 811 Index 866 891
